Objectives : The present study aimed to examine the analgesic effect of electroacupuncture(EA) applied to the brook point of the Liver meridian in the rat model of inflammatory pain and to investigate involvement of endogenous opioid in the EA-induced analgesia. **Methods :** Knee arthritis was induced by injection of 125 μ l of complete Freund's adjuvant into the knee joint cavity unilaterally. To examine the level of pain, weight bearing forces(WBFs) of affected limb was measured. EA treatment was given at the LR2, LI4 or non-acupoint on the contralateral limb with frequency of 2 Hz and intensity of 2 mA under gaseous anesthesia. **Results :** After induction of arthritis, rats subsequently showed a reduced stepping force of the affected hindlimb due to a painful knee. EA applied to the LR2 point on the contralateral hind limb produced a significant improvement of stepping force of the hind limb lasting for at least 2 h, and this effect was equivalent to that obtained by 5 mg/kg of oral indomethacin. The effect of EA was specific to the acupoint since it could not be mimicked by EA applied to the LI4 point or the arbitrary non-acupoint. The analgesic effect was blocked by pretreatment with naltrexone(10 mg/kg, i.p.). **Conclusions :** These results suggest that acupuncture applied to LR2, brook point of Liver meridian suppresses inflammatory pain in a rat model of knee arthritis and this effect seems to be mediated by endogenous opioid systems.

Key words : electroacupuncture, brook point, arthritis, complete freund's adjuvant, opioid

Introduction

Acupuncture has been used to ameliorate health and is still used to treat many conditions, including chronic and acute pain¹⁾. Among the symptoms of arthritis, chronic pain is the most serious and is difficult to treat in a satisfactory manner²⁾. To investigate the mechanisms underlying acupuncture

analgesia, many studies have been conducted using electroacupuncture(EA) on various experimental animal models³⁻⁵⁾. The most significant finding from these studies, perhaps, is that EA-induced analgesia is found to be at least partly reversed by a systemic injection of naloxone, a non-selective opioid antagonist. The result of the early studies suggests that the endogenous opioid system mediates a part of EA-induced

analgesia^{6,7)}. Furthermore, the naloxone reversible component of the analgesia seems to depend on the frequency of EA⁸⁾, suggesting the existence of a specific set of sensory neurons that activate the endogenous opioid system.

In the classical theory of acupuncture, the five transport points are the well, brook, stream, river and sea points of the twelve meridians and one of the most important groups of acupuncture points. The five transport points play an important role in the formation of many acupuncture prescriptions¹⁾. Brook point, also known as spring point is the second of the five transport points and is located in the area of the metacarpophalangeal joint of the hand or metatarsophalangeal joint of the foot with the exception of Kidney meridian(KI2). According to the Classic of Difficulties, the brook points are indicated for heat in the body⁹⁾. Because heat along with pain, redness, immobility and swelling is one of key symptoms of inflammation, brook points could be one of options to reduce heat symptom in acupuncture treatment.

To demonstrate the analgesic effect of EA applied to the brook point of Liver meridian in rats, the present study used an arthritis model induced by injection of complete Freund's adjuvant(CFA). CFA arthritis model is a popular laboratory animal model of chronic pain since it has many of the pathological features in common with human rheumatoid arthritis(RA)¹⁰⁾. Acupuncture has been offered as an alternative treatment for the chronic pain syndromes related to RA in humans¹¹⁾.

Thus, there are few studies to investigate the effects and underlying mechanisms of brook points in the inflammatory pain. In the present study, we aimed to investigate the effect of LR2 on the pain behavior and involvement of endogenous opioids in LR2-induced analgesia in the rat model of inflammatory pain.

Materials and Methods

1. Animals

Male Sprague-Dawley rats(weighing 190~210 g) were housed in cages(2~3 per cage) with soft bedding and were

provided free access to food and water under 12~12 hour reversed light-dark cycle(dark cycle: 08:00~20:00). All experimental procedures were carried out in accordance with the Animals(Scientific Procedures) Act 2008(Korea) and all complied with the recommendations of the National Institute of Health's Guide for the Care and Use of Laboratory Animals. The study was also approved by the Ethics Committee on Animal Research at Pusan National University(PNU-2016-1219). The rats were anesthetized under isoflurane anesthesia(3% to induce and 1.5% to maintain in mixed N₂O/O₂ air).

2. Induction of arthritis

CFA arthritis was induced by injecting 125 μ l of a mixture of 62.5 μ l of saline, and 250 μ g of suspended heat-killed *Mycobacterium butyricum*(Difco, Detroit MI, USA) in 62.5 μ l of incomplete Freund's adjuvant(Difco, Detroit MI, USA) into the synovial cavity of the right knee joint.

3. Behavioral test

To evaluate the level of pain in the arthritic knee, we measured the amount of weight bearing by the affected hind limb on rats as our method recently used¹²⁾. The rat was allowed to walk through a long and narrow acrylic path (width×height×length: 10×12×80 cm). The rectangular shaped plate of the electronic balance(Sartorius, BP-1200, Germany) was placed to cover a half-width of the floor at the mid way point of the walking path so that only the limbs of one side would step on the balance. The degree of analgesia was expressed as a percentage of relatively improved foot stepping force and was determined as follows:

$$\frac{\text{Post-treatment value} - \text{Pre-treatment value}}{\text{Maximum possible value} - \text{Pre-treatment value}} \times 100$$

Maximum possible value was expressed as the foot stepping force on each normal rat's hind limb before the induction of arthritis. Foot stepping force was expressed as weight bearing ratio to body weight.

4. Electroacupuncture

Under isoflurane anesthesia, two stainless steel needles

(0.25 mm diameter, 30 mm length) mounted on a holder with a 1-mm separation between the tips were inserted into three different points, LR2, LI4 or arbitrary non-acupoint and electrical stimulation was applied by a Grass S88 stimulator(Grass Medical Instruments, Quincy, MI, USA) equipped with the isolator for 30 min. Trains of 4 pulses(10 ms square wave pulses, 50 Hz of intra-train frequency) repeated at a rate of 2 Hz were delivered at an intensity of 2 mA. LR2 point was located on the margin of the web between the 1st and 2nd toes. LI4 point was located on the dorsal aspect at the midpoint of the line bisecting the angle between the 1st and 2nd metacarpal bones¹³⁾. The arbitrary non-acupoint was located on the dorsal aspect of the left foot.

5. Drugs

In order to determine whether the effect of EA was mediated by endogenous opioids, naltrexone(10 mg/kg, Sigma) was intraperitoneally injected 1.5 h before the beginning of EA. In addition, to assess the effects of indomethacin on the arthritis, 2 and 5 mg/kg of indomethacin were orally administrated.

Fig. 1. Changes in weight bearing of the affected hindlimb after the induction of arthritis.

Foot stepping force was measured and expressed as weight bearing ratio to body weight. This shows the average values($\pm$ SEM) of weight bearing ratio of the hindlimb of a group of 9 rats one hour before(Pre) and at various times after the induction of arthritis. Asterisks indicate values significantly different from the preoperative value(Pre)($p < 0.05$, one-way repeated measures ANOVA followed by Dunnett's post-hoc test).

6. Statistical analysis

Data are expressed as mean $\pm$ SEM. Statistical analyses were conducted by the one-way repeated measures analysis of Variance(ANOVA) followed by the Dunnett's post-hoc test, or two-way repeated measures ANOVA followed by the Duncan's all pairwise multiple comparison. A p value of less than 0.05 was considered to be statistically significant.

Results and Discussion

As shown in Fig. 1, the weight bearing on the normal rat's hind limb reached about 53% of the rat's total body weight. One day after the induction of arthritis, the stepping force on the affected hind limb was maximally reduced to such an extent that rats did not put any weight on the foot. Once induced, arthritic pain lasted for the next several weeks. We reasoned that the reduced weight bearing on the foot after the induction of knee arthritis was because rats were trying to avoid bearing weight on the affected foot due to pain

Fig. 2. Effect of indomethacin on weight bearing of the hindlimb in rats with arthritis.

At the 3rd, 4th, and 5th day after the induction of arthritis, either distilled water(DW) alone, 2 mg/kg of indomethacin(Indo 2 mg), or 5 mg/kg of indomethacin(Indo 5 mg) was orally administrated in random order in different rats in 8 rats with arthritis. Consequently, all 8 rats received each of the three injections on a different day in a randomized crossover manner. Symbols*and+ denote values significantly different from the pre-injection value (-1 h) and from the control(DW) group, respectively($p < 0.05$, two-way repeated measures ANOVA followed by Duncan's multiple comparison). indo; indomethacin.

associated with the knee arthritis. To evaluate the validity of using the reduction of foot stepping force as an index for arthritic pain, the effect of oral indomethacin on the stepping force was examined. As shown in Fig. 2, administrations of both 2 and 5 mg/kg of indomethacin significantly restored the reduced foot stepping force for at least 2 h. This effect of indomethacin can be interpreted as producing an analgesic effect so that rats can now put more weight on the foot. To examine the effect of EA on the stepping force, EA was applied to an acupoint for 30 min under isoflurane anesthesia. As shown in Fig. 3, only EA applied to the LR2 point significantly restored the reduced foot stepping force at a half-, one- and two-hour post-stimulus time points. These data suggest that EA applied to the LR2 point produces an analgesic effect in the knee arthritis pain model. The effect peaks at one hour after the termination of EA and decreases slowly. The magnitude of EA-induced analgesia is equivalent to that obtained by 5 mg/kg of oral indomethacin. Furthermore, the analgesic effect of EA was occurred in a stimulus point-specific manner. EA applied to the LR2 point produced analgesia but EA applied to LI4 or nearby non-acupoint did

Fig. 3. Effect of EA on weight bearing of the hindlimb in rats with arthritis.

At the 3rd, 4th, 5th and 6th day after the induction of arthritis, either anesthesia alone, EA at the LR2 point, EA at the LI4 point, or EA at the arbitrary non-acupoint(NA) was applied in random order in different rats in 8 rats with arthritis. Consequently, all 8 rats received each of the four procedures in a randomized crossover manner. Symbols*and + denote values significantly different from the pre-stimulus value(-1 h) and from the control (Anes Only) group, respectively($p < 0.05$, two-way repeated measures ANOVA followed by Duncan's multiple comparison).

not. LI4 point is known from previous studies to reduce thermal pain threshold¹⁴⁾ and to release endogenous opioids^{3,6,7)}. Although LI4 point is known to produce acupuncture analgesia in some conditions, the effect of EA stimulation applied to LI4 in the present study showed no significant difference between anesthesia control group or a non-acupoint group. The different conditions of EA parameter, animal model and/or behavioral test may account for the inconsistent results.

Endogenous opioid hypothesis in acupuncture analgesia proposes that acupuncture stimulation activates the endogenous opioid system to raise the circulating endorphin level. Supporting evidence includes the observation that an injection of naloxone, an opiate antagonist, reverses acupuncture analgesia in mice⁶⁾ as well as in man⁷⁾. Furthermore, naloxone blockade of EA was found to be frequency dependent⁸⁾ and the effect of EA at different frequencies was mediated by different subtypes of opiate receptors^{8,15,16)}. It was later found that serotonergic and noradrenergic pain inhibitory systems play additional roles in acupuncture analgesia^{17,18)}.

On the other hand, other studies failed to reverse EA induced analgesia by opiate antagonists, such as naloxone or

Fig. 4. Effect of naltrexone on EA-induced analgesia.

8 rats were randomly divided into two groups. In one group of 4 rats, EA was applied to the LR-2 point 1.5 h after the injection of naltrexone. In other group of 4 rats, EA was applied to the LR-2 point 1.5 h after the injection of saline. Therefore, all 8 rats received naltrexone and saline with EA within 2 days in a randomized crossover manner. Symbols*and + denote values significantly different from the pre-treatment value(-1 h) and from NTX + EA group, respectively($p < 0.05$, two-way repeated measures ANOVA followed by Duncan's multiple comparison).

naltrexone, in rabbits¹⁹⁾, in rats^{5,12)}, or in humans²⁰⁾. Furthermore, opiate antagonists sometimes potentiate EA analgesia in rats^{5,21)}. Therefore, the issue of whether or not EA induced analgesia is mediated by endogenous opioids is not completely settled.

The effect of pretreatment with naltrexone on the analgesic effect of EA was examined. As shown in Fig. 4, EA applied to the LR2 point significantly restored the reduced foot stepping force in only saline-pretreated arthritis rats. These data suggest that the effect of EA can be blocked by naltrexone. Using the knee arthritis model, we demonstrated that EA produced a long lasting analgesic effect and the effect of EA could be mediated by the endogenous opioid system. Results of present study is in line with the findings that acupuncture can alleviate the knee pain associated with the development of RA^{22,23)}. In addition, the present results is consistent with the facts that the analgesic effect of EA is mediated by endogenous opioids^{6,7,24)}.

The reduced weight bearing in the arthritis is one of the most commonly observed functional disabilities in arthritic animals and humans. In this study, we measured the weight bearing by the affected limb to assess the level of pain in the arthritis^{25,26)}. Previously, Min et al.²⁵⁾ measured changes in weight bearing of the foot by having rat voluntarily walk through a chamber. They used this method in rats with acute and mild arthritis recovered relatively quickly(3 days) while we used it in rats with chronic and severe arthritis lasting for the several weeks. These facts suggest that this technique is useful for the assessment of both acute and chronic arthritis models. However, it was difficult to measure the effects of analgesic treatments for arthritic pain within 2 days after the induction of CFA arthritis, since at those periods the level of pain was so severe that rats could not put any weight on the hind limb.

Conclusion

In summary, we demonstrated the analgesic effect of EA applied to brook point of the Liver meridian on the knee

arthritis pain model. The effect lasted for at least 2 h after the termination of EA and the magnitude of the peak effect was equivalent to that obtained by 5 mg/kg of oral indomethacin. The analgesic effect was induced by EA applied to the acupoint remote from the affected limb in a stimulus point-specific manner. Furthermore, the effect of EA was likely mediated by endogenous opioid system.

국문초록

목적 : 이 연구는 흰쥐 염증성 통증 모델에서 족궤음간경의 형혈 전침의 진통효과를 조사하고 이 전침의 진통효과에 내인성 오피오이드가 관여되어 있는지 조사하고자 하였다. **방법 :** 무릎 관절염은 125 μ l complete Freund's adjuvant를 흰쥐의 한쪽 무릎관절강에 주입하여 유도하였다. 통증 정도를 검사하기 위해 관절염을 유도한 쪽 뒷다리의 weight bearing forces(WBFs)를 측정하였다. 전침은 건측 행간, 합곡, 또는 뒷다리의 비경혈에 가스 마취하에서 2 Hz, 2 mA 자극조건으로 처치하였다. **결과 :** 관절염을 유도한 이후에, 점차적으로 무릎에 통증이 증가하기 때문에 관절염을 유발한 쪽 뒷발로 딛는 압력이 감소하였다. 건측 행간에 전침 자극을 한 군에서 전침 자극 후 최소 2시간까지 유의하게 WBF가 증가하였으며, 이 효과는 구강으로 투여한 indomethacin 5 mg/kg의 효과에 해당하였으며, 이 전침의 효과는 합곡이나 비경혈에서는 나타나지 않았다. 아울러 이 진통효과는 오피오이드 길항제인 naltrexone(10 mg/kg, i.p.)을 전처치했을 때 차단되었다. **결론 :** 이상의 결과는 족궤음간경의 형혈인 행간 자침이 흰쥐 관절염 모델에서 염증성 통증을 억제하는 효과가 있음을 보여주며, 이 효과는 내인성 오피오이드 시스템이 매개하는 것으로 보인다.
